High density lipoprotein (HDL) particles, containing apolipoprotein E (apo E), were purified from rat and rabbit plasma by sequential precipitation with polyanions, including phosphotungstate. Perfusion of rat liver with these purified HDL3 particles showed enrichment of apo E and albumin, but only a marginal enrichment of cholesterol. In contrast, perfusion of rabbit liver with these HDL3 particles resulted in enrichment of all three lipoproteins. Perfusion of rat liver with HDL3 particles produced marked increases in conversion of [14C]acetate into fatty acid and decrease into CO₂. The half-life of [14C]acetate in the perfusate was significantly prolonged by perfusion with HDL3. Perfusion of rat liver with HDL3 resulted in enrichment of radioactivity in phospholipid and neutral lipids but not in protein. In contrast, perfusion of rabbit liver with HDL3 resulted in a significant increase in incorporation of radioactivity into the protein of HDL3. Rabbit liver perfused with prelabelled HDL3 was able to transfer label to the isolated human VLDL and LDL by receptor-mediated processes. Rat liver, on the other hand, was unable to transfer label to the LDL. These findings suggested that the receptor for apo E on rat liver cell membranes was of relatively low affinity and that this receptor was absent or of low density on rabbit liver cell membranes. After much anticipation, Google has launched its self-driving car project, called Waymo. This is exciting for two reasons. One, we want to see if our competitors are able to beat us at our own game (we know they can't be far behind). Two, all of our car manufacturing futures hang in the balance as Google's self-driving car rises to the top. It could disrupt the entire auto industry. Waymo isn't Google's first stab at autonomous vehicles. Previously, it announced plans to work with Jaguar Land Rover on "self-driving" technology, which means their cars will go where they're asked by the driver. Any test vehicles from either party will be able to read traffic signals
